

APPLICATION LAYER

Traffic, Traffic Everywhere

Web and HTTP

First, a review...

- *web page* consists of *objects*
- object can be HTML file, JPEG image, Java applet, audio file,...
- web page consists of *base HTML-file* which includes *several referenced objects*
- each object is addressable by a *URL*, e.g.,

`www.neu.edu.cn/softwarecollege/pic.gif`

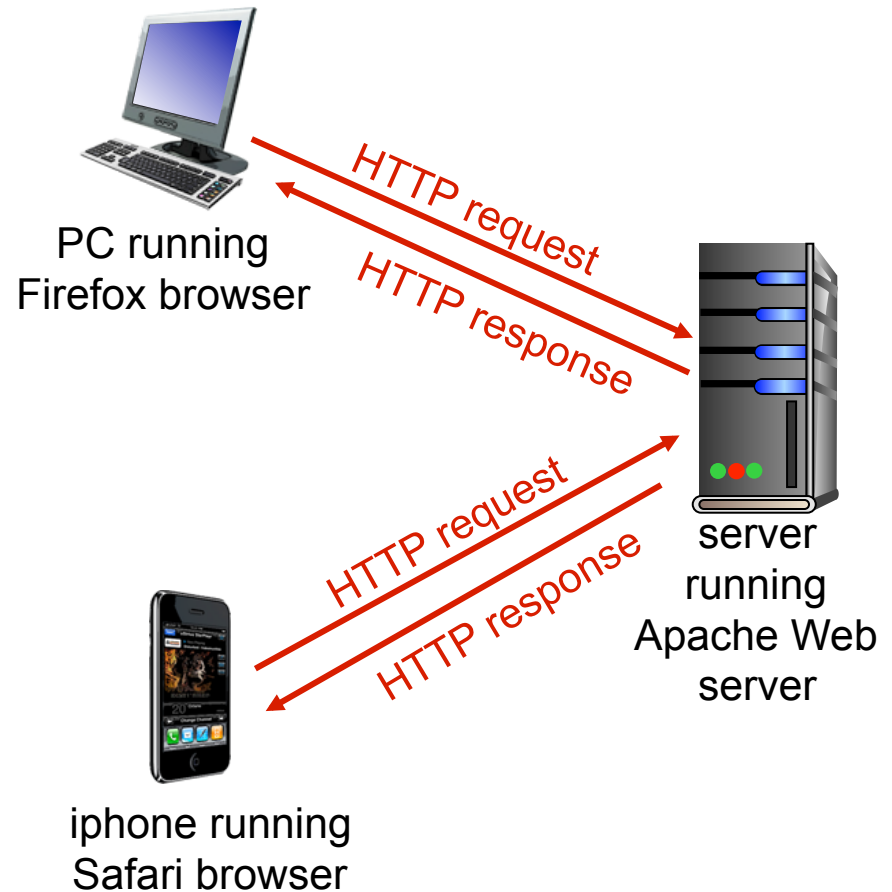

host name

path name

HTTP overview

hypertext transfer protocol

- Web's application layer protocol
- client/server model
 - ▣ **client:** browser that requests, receives, (using HTTP protocol) and “displays” Web objects
 - ▣ **server:** Web server sends (using HTTP protocol) objects in response to requests

HTTP overview (continued)

uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages (application-layer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

HTTP is “stateless”

- server maintains no information about past client requests

aside protocols that maintain “state” are complex!

- ❖ past history (state) must be maintained
- ❖ if server/client crashes, their views of “state” may be inconsistent, must be reconciled

HTTP connections

non-persistent HTTP

- at most one object sent over TCP connection
 - ▣ connection then closed
- downloading multiple objects required multiple connections

persistent HTTP

- multiple objects can be sent over single TCP connection between client, server

HTTP request message

- two types of HTTP messages: *request, response*
- **HTTP request message:**
 - ASCII (human-readable format)

request line
(GET, POST,
HEAD commands)

header
lines

carriage return,
line feed at start
of line indicates
end of header lines

```
GET /index.html HTTP/1.1\r\n
Host: www-net.cs.umass.edu\r\n
User-Agent: Firefox/3.6.10\r\n
Accept: text/html,application/xhtml+xml\r\n
Accept-Language: en-us,en;q=0.5\r\n
Accept-Encoding: gzip,deflate\r\n
Accept-Charset: ISO-8859-1,utf-8;q=0.7\r\n
Keep-Alive: 115\r\n
Connection: keep-alive\r\n
\r\n
```

carriage return character
line-feed character

The diagram illustrates the structure of an HTTP request message. It shows a sequence of lines: a request line, followed by header lines, and a final blank line. Annotations with arrows point to specific parts of the message: 'request line (GET, POST, HEAD commands)' points to the first line; 'header lines' points to the block of lines between the request line and the final blank line; 'carriage return, line feed at start of line indicates end of header lines' points to the '\r\n' at the beginning of the final blank line; 'carriage return character' points to the '\r' in the first line; and 'line-feed character' points to the '\n' in the first line.

Method types

HTTP/1.0:

- GET
- POST
- HEAD
 - ▣ asks server to leave requested object out of response

HTTP/1.1:

- GET, POST, HEAD
- PUT
 - ▣ uploads file in entity body to path specified in URL field
- DELETE
 - ▣ deletes file specified in the URL field

HTTP response message

status line
(protocol
status code
status phrase)

header
lines

data, e.g.,
requested
HTML file

```
HTTP/1.1 200 OK\r\n
Date: Sun, 26 Sep 2010 20:09:20 GMT\r\n
Server: Apache/2.0.52 (CentOS)\r\n
Last-Modified: Tue, 30 Oct 2007 17:00:02 GMT
\r\n
ETag: "17dc6-a5c-bf716880"\r\n
Accept-Ranges: bytes\r\n
Content-Length: 2652\r\n
Keep-Alive: timeout=10, max=100\r\n
Connection: Keep-Alive\r\n
Content-Type: text/html;
    charset=ISO-8859-1\r\n
\r\n
data data data data data ...
```

HTTP response status codes

- ❖ status code appears in 1st line in server-to-client response message.
- ❖ some sample codes:

200 OK

- ▣ request succeeded, requested object later in this msg

301 Moved Permanently

- ▣ requested object moved, new location specified later in this msg (Location:)

400 Bad Request

- ▣ request msg not understood by server

404 Not Found

- ▣ requested document not found on this server

505 HTTP Version Not Supported

User-server state: Cookies

Many websites use cookies.

four components:

- 1) cookie header line of HTTP *response* message
- 2) cookie header line in next HTTP *request* message
- 3) cookie file kept on user's host, managed by user's browser
- 4) back-end database at Web site

example:

- Susan always access Internet from PC
- visits specific e-commerce site for first time
- when initial HTTP requests arrives at site, site creates:
 - ▣ unique ID
 - ▣ entry in backend database for ID

Cookies – How it works

what cookies can be used for:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

cookies and privacy:

- ❖ cookies permit sites to learn a lot about you
- ❖ you may supply name and e-mail to sites

how to keep “state”:

- ❖ protocol endpoints: maintain state at sender/receiver over multiple transactions
- ❖ cookies: http messages carry state

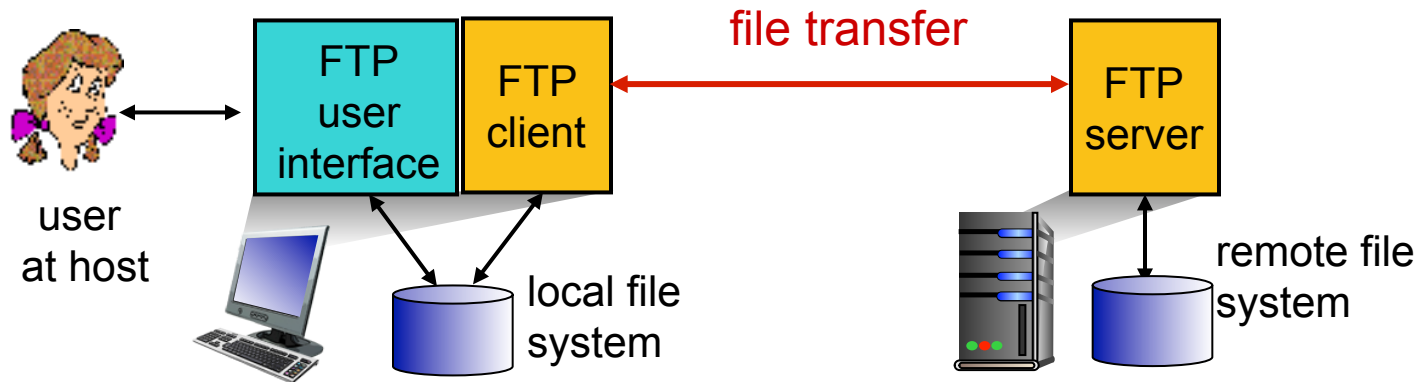

Web caches (Proxy Server)

goal: satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
 - ▣ object in cache: cache returns object
 - ▣ else cache requests object from origin server, then returns object to client

FTP: the file transfer protocol

- ❖ transfer file to/from remote host
- ❖ client/server model
 - **client**: side that initiates transfer (either to/from remote)
 - **server**: remote host
- ❖ ftp: RFC 959
- ❖ ftp server: port 21

FTP: separate control, data connections

- FTP client contacts FTP server at port 21, using TCP
- client authorized over control connection
- client browses remote directory, sends commands over control connection
- when server receives file transfer command, **server** opens 2nd TCP data connection (for file) to client
- after transferring one file, server closes data connection

- ❖ server opens another TCP data connection to transfer another file
- ❖ control connection: **“out of band”**
- ❖ FTP server maintains “state”: current directory, earlier authentication

DNS: Domain Name System

people: many identifiers:

- ▣ SSN, name, passport #

Internet hosts, routers:

- ▣ IP address (32 bit) - used for addressing datagrams
- ▣ “name”, e.g., `www.yahoo.com` - used by humans

Q: how to map between IP address and name, and vice versa ?

Domain Name System:

- ▣ *distributed database*
implemented in hierarchy of many *name servers*
- ▣ *application-layer protocol*: hosts, name servers communicate to *resolve* names (address/name translation)
 - ▣ note: core Internet function, implemented as application-layer protocol
 - ▣ complexity at network's “edge”

DNS: Services & Structure

DNS services

- hostname to IP address translation
- host aliasing
 - ▣ canonical, alias names
- mail server aliasing
- load distribution
 - ▣ replicated Web servers: many IP addresses correspond to one name

why not centralize DNS?

- single point of failure
- traffic volume
- distant centralized database
- maintenance

DNS: A Distributed, Hierarchical Database

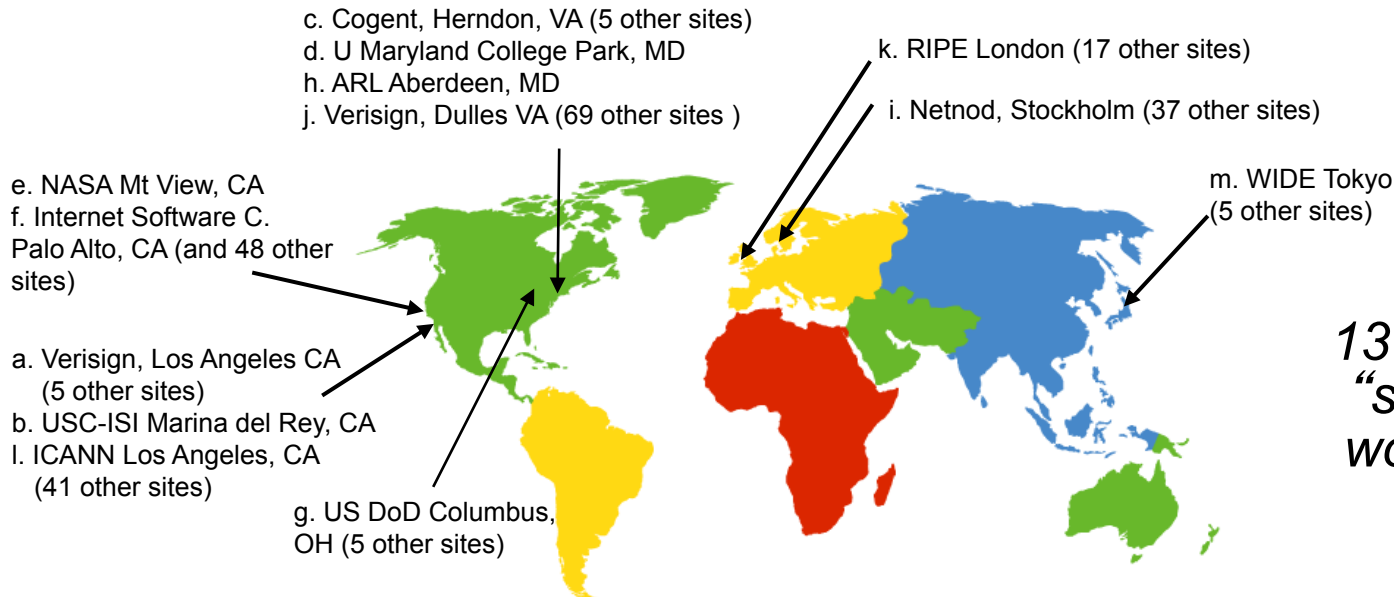

client wants IP for www.amazon.com; 1st approx:

- client queries root server to find com DNS server
- client queries .com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for www.amazon.com

DNS: Root Name Servers

- contacted by local name server that can not resolve name
- root name server:
 - ▣ contacts authoritative name server if name mapping not known
 - ▣ gets mapping
 - ▣ returns mapping to local name server

*13 root name
“servers”
worldwide*

TLD, authoritative servers

top-level domain (TLD) servers:

- ▣ responsible for com, org, net, edu, aero, jobs, museums, and all top-level country domains, e.g.: uk, fr, ca, jp
- ▣ Network Solutions maintains servers for .com TLD
- ▣ Educause for .edu TLD

authoritative DNS servers:

- ▣ organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts
- ▣ can be maintained by organization or service provider

Local DNS Name Server

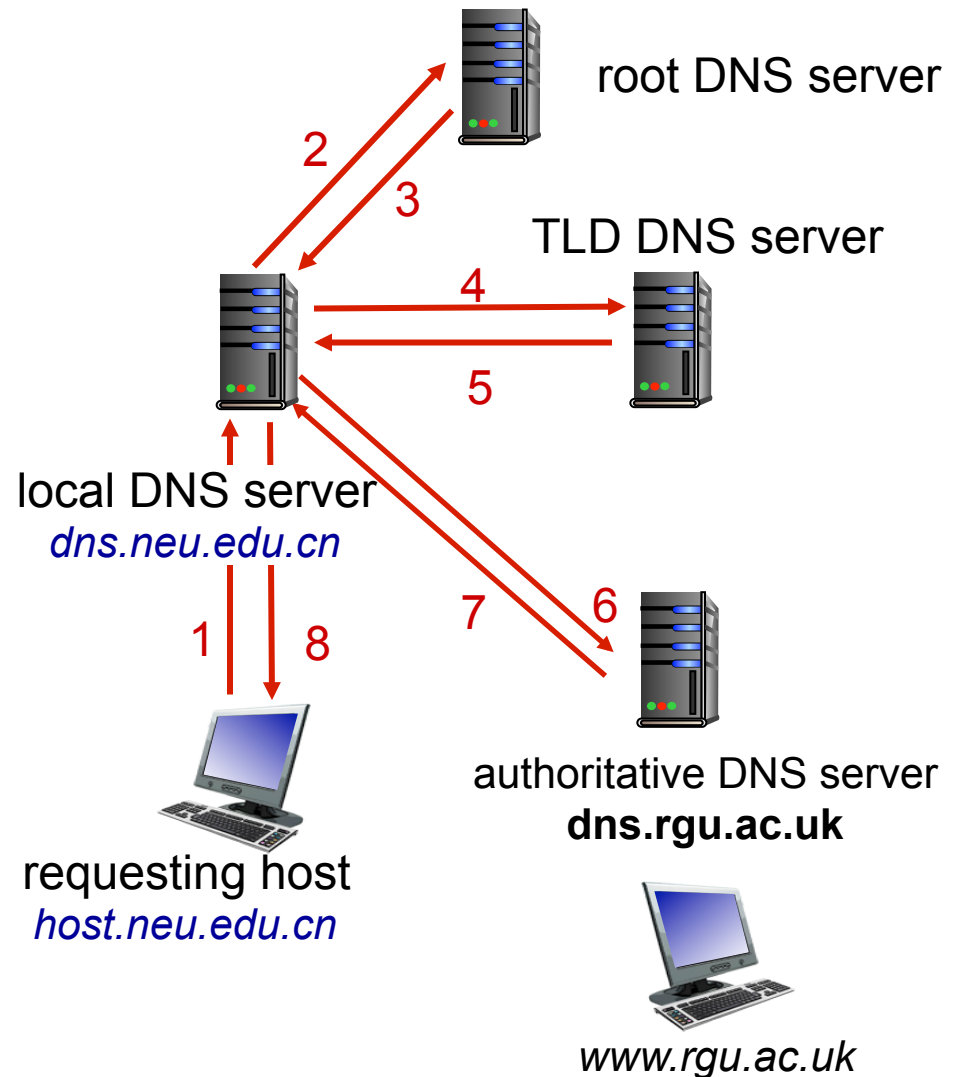

- does not strictly belong to hierarchy
- each ISP (residential ISP, company, university) has one
 - ▣ also called “default name server”
- when host makes DNS query, query is sent to its local DNS server
 - ▣ has local cache of recent name-to-address translation pairs (but may be out of date!)
 - ▣ acts as proxy, forwards query into hierarchy

DNS: name resolution - Iterated

- host at neu.edu.cn wants IP address for www.rgu.ac.uk

iterated query:

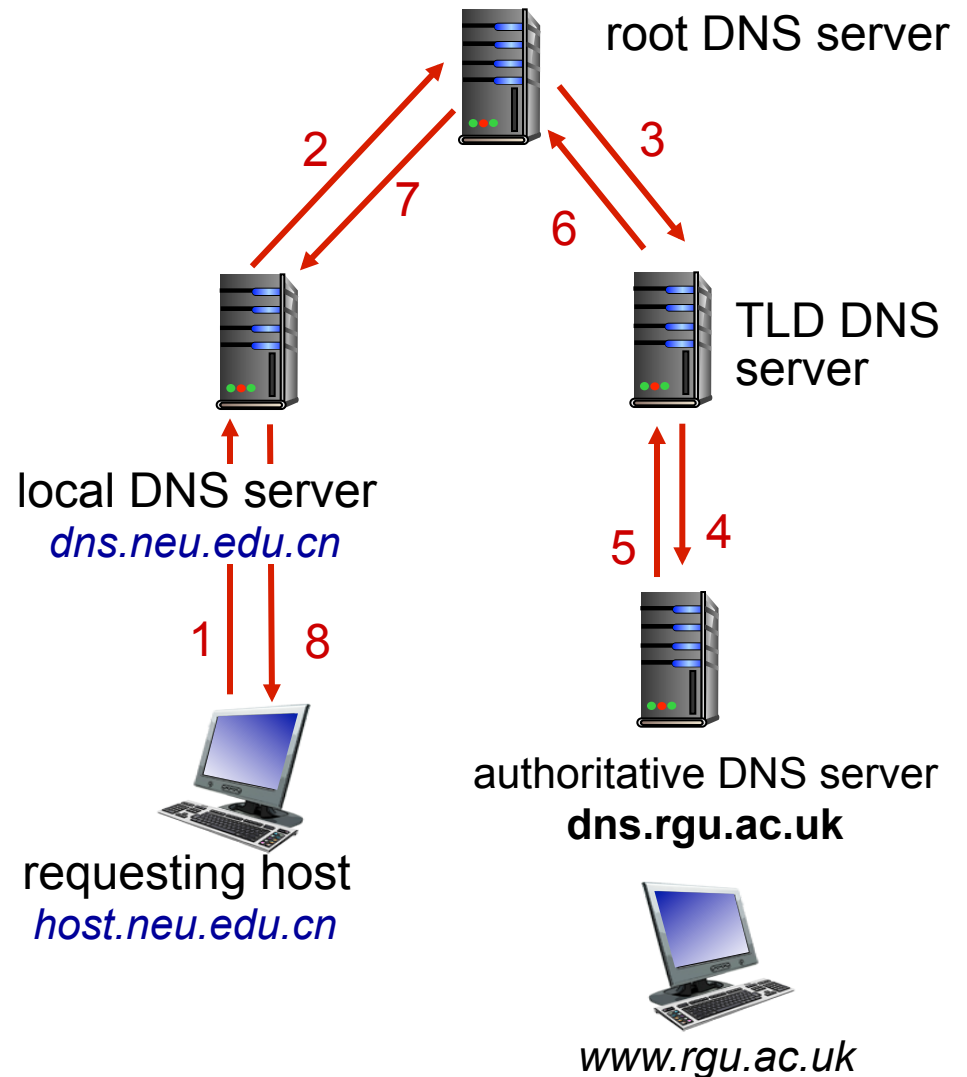

- ❖ contacted server replies with name of server to contact
- ❖ “I don’t know this name, but ask this server”

DNS: name resolution - recursive

recursive query:

- ❖ puts burden of name resolution on contacted name server
- ❖ heavy load at upper levels of hierarchy?

DNS: caching, updating records

- once (any) name server learns mapping, it *caches* mapping
 - ▣ cache entries timeout (disappear) after some time (TTL)
 - ▣ TLD servers typically cached in local name servers
 - thus root name servers not often visited
- cached entries may be *out-of-date* (best effort name-to-address translation!)
 - ▣ if name host changes IP address, may not be known Internet-wide until all TTLs expire
- update/notify mechanisms proposed IETF standard
 - ▣ RFC 2136

DNS records

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

type=A

- **name** is hostname
- **value** is IP address

type=NS

- ▣ **name** is domain (e.g., foo.com)
- ▣ **value** is hostname of authoritative name server for this domain

type=CNAME

- **name** is alias name for some “canonical” (the real) name
- **www.ibm.com** is really **servereast.backup2.ibm.com**
- **value** is canonical name

type=MX

- **value** is name of mailserver associated with **name**

Attacking DNS

DDoS attacks

- Bombard root servers with traffic
 - ▣ Not successful to date
 - ▣ Traffic Filtering
 - ▣ Local DNS servers cache IPs of TLD servers, allowing root server bypass
- Bombard TLD servers
 - ▣ Potentially more dangerous

Redirect attacks

- ❖ Man-in-middle
 - Intercept queries
- ❖ DNS poisoning
 - Send bogus replies to DNS server, which caches

Exploit DNS for DDoS

- ❖ Send queries with spoofed source address: target IP
- ❖ Requires amplification
